

Basics of Geometric Deep Learning

Symmetries & Machine Learning

Representations of Geometric Data & Symmetries

2D Rotations

$$R_\alpha = \begin{bmatrix} \cos(\alpha) & \sin(\alpha) \\ -\sin(\alpha) & \cos(\alpha) \end{bmatrix}$$

Permutations

$$[x_1, x_2, x_3]^t$$

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} = P$$

$$\begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix} = Q$$

Equivariant Neural Networks

Idea

Equivariance

A feature map $\Phi : \mathbb{R}^n \rightarrow \mathbb{R}^n$ is **equivariant** with respect to P if

$$P \circ \Phi = \Phi \circ P$$

Equivariant Neural Networks

Composition

$\Phi = \phi_m \circ \tilde{f}_{m-1} \circ \phi_{m-1} \circ \dots \circ \tilde{f}_1 \circ \phi_0$
of equivariant **linearities** ϕ_i and equivariant **activations** \tilde{f}_i

Breaking Symmetry

Point-wise Activations

$$\tilde{f}(x_1, \dots, x_n) = (f(x_1), \dots, f(x_n))$$

e.g. $f = \text{ReLU}, \text{sigmoid}, \text{tanh}, \dots$

ReLU is **equivariant** with respect to **permutation** representations

ReLU is **not equivariant** with respect to **rotations**. Indeed ↓

E.g.:

$$\text{ReLU} \circ R_{\frac{\pi}{2}} \left(\begin{bmatrix} 0 \\ 1 \end{bmatrix} \right) = \text{ReLU} \left(\begin{bmatrix} -1 \\ 0 \end{bmatrix} \right) = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$=$$

$$R_{\frac{\pi}{2}} \circ \text{ReLU} \left(\begin{bmatrix} 0 \\ 1 \end{bmatrix} \right) = R_{\frac{\pi}{2}} \left(\begin{bmatrix} 0 \\ 1 \end{bmatrix} \right) = \begin{bmatrix} -1 \\ 0 \end{bmatrix} \neq \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Research Question

- Given **specific symmetries**, need to guess **viable activations** to design **equivariant layers**?
- Or manage to **completely describe** the following correspondence?

$$[?] \text{ (Symmetries } P, \text{ Functions } f) \longleftrightarrow \text{Equivariant Activations } \tilde{f} \text{ [?]}$$

Main Theorem

T-Monomial Matrices

A **T-monomial matrix** has only one non-zero element for each column and row and it lies in T . Where $T \subseteq \mathbb{R}$ is a multiplicative group.

E.g.:

$T = \langle 1 \rangle$	$T = \langle \pm 1 \rangle$	$T = \mathbb{R}_{>0}$
$\begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & -1 & 0 \end{bmatrix}$	$\begin{bmatrix} 0 & 0 & 1 \\ \sqrt{2} & 0 & 0 \\ 0 & \frac{1}{3} & 0 \end{bmatrix}$

T-Equivariant Functions

A function $f : \mathbb{R} \rightarrow \mathbb{R}$ is **T-equivariant** if

$$f(tx) = tf(x)$$

for each $x \in \mathbb{R}$ and $t \in T$.

E.g.:

$T = \langle 1 \rangle$	$T = \langle \pm 1 \rangle$	$T = \mathbb{R}_{>0}$
Each f	Each odd f	ReLU
		LeakyReLU
		...

Claim 1 - Informal

Assume f to be **non-affine** and **continuous**. Then

$$(T\text{-monomial } P, T\text{-equivariant } f) \iff \text{Equivariant Activations } \tilde{f}$$

Claim 2 - Informal

Let P belong to a **compact** set of symmetries. Then, up to coordinate change, P is a **signed-permutation matrix**. If f is not odd, P is a **permutation matrix**.

Relevant Implications

Geometric Invariant Graph Networks (IGNs)

A **Geometric IGN** is a neural network $\Phi : (\mathbb{R}^n)^{\otimes 2} \otimes \mathbb{R}^3 \rightarrow \mathcal{Y}$ simultaneously equivariant with respect to **permutations** P and **rotations** R_α .

E.g.:

$$P \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = \begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix}, \quad R_{\frac{\pi}{2}} \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = \begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix}, \quad \text{and} \quad \Phi \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = \begin{bmatrix} \color{red}{\square} \\ \color{blue}{\square} \\ \color{green}{\square} \end{bmatrix}$$

$$\Phi \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = \Phi \circ P \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = P \circ \Phi \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = P \left(\begin{bmatrix} \color{red}{\square} \\ \color{blue}{\square} \\ \color{green}{\square} \end{bmatrix} \right) = \begin{bmatrix} \color{blue}{\square} \\ \color{red}{\square} \\ \color{green}{\square} \end{bmatrix}$$

$$\Phi \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = \Phi \circ R_{\frac{\pi}{2}} \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = R_{\frac{\pi}{2}} \circ \Phi \left(\begin{bmatrix} \bullet \\ \bullet \\ \bullet \end{bmatrix} \right) = R_{\frac{\pi}{2}} \left(\begin{bmatrix} \color{red}{\square} \\ \color{blue}{\square} \\ \color{green}{\square} \end{bmatrix} \right) = \begin{bmatrix} \color{green}{\square} \\ \color{red}{\square} \\ \color{blue}{\square} \end{bmatrix}$$

Relevant Corollaries

Non-existence Results

Geometric IGNs with non-affine point-wise activations are **trivial**.

A common mitigation strategy is to require equivariance on only a finite subset of symmetries. This approach leads to networks which are

- approximately equivariant** with respect to the entire group of symmetries
- non-trivial** and completely described by the following **Corollary** of **Claim 2** ↓

Finite Groups of Symmetries

Let G be a **finite** set of symmetries and suppose f non-odd non-affine. Then each hidden representation is of the form

$$\mathbb{R}^{G/H_1} \times \dots \times \mathbb{R}^{G/H_m}$$

for a finite number of symmetry subgroups $H_i < G$.

Future Directions

- Robustness of approximate equivariance**, i.e., satisfying equivariance on a finite subset of symmetries implies bounds on $\|P \circ \Phi - \Phi \circ P\|$. Experimental results are positive, no theoretical results are known to the authors.
- Apply the proposed approaches to models with activations **beyond real point-wise ones**. E.g.: (i) complex neural networks with complex point-wise activations similar to Harmonic Networks [2] or (ii) the more general Steerable CNNs [1].
